SettleSync

Guide for reviewers and testers

SettleSync lets freelancers send invoices that get paid in USDC or XLM on Stellar and mark themselves paid automatically. This guide explains what it is and walks you through testing it in about 15 minutes.

Live site: **settlesync-silk.vercel.app** Code: **github.com/Rohanmd13/settlesync** Rohan M D · 28 Oct 2026

At a glance

SettleSync is a non-custodial invoicing website on Stellar for freelancers, agencies and the clients who pay them. Each payment carries its invoice number in the Stellar memo, so SettleSync knows exactly which invoice it paid, marks it paid by itself, and exports a ledger ready for an accountant. Built in India, for everywhere.

Quick facts:

- **Networks:** Stellar Main Net (real money) and Testnet (free test money). The site follows whichever network your wallet is on.
- **Wallets:** Freighter, Albedo, xBull, LOBSTR, Hana, Rabet and more, through Stellar Wallets Kit. Albedo needs nothing installed.
- **Assets:** USDC and XLM.
- **No sign-up, no server database:** your wallet is your login. SettleSync never holds anyone's money.
- **Stack:** React + Vite, Stellar JS SDK, Horizon, deployed on Vercel.

The problem

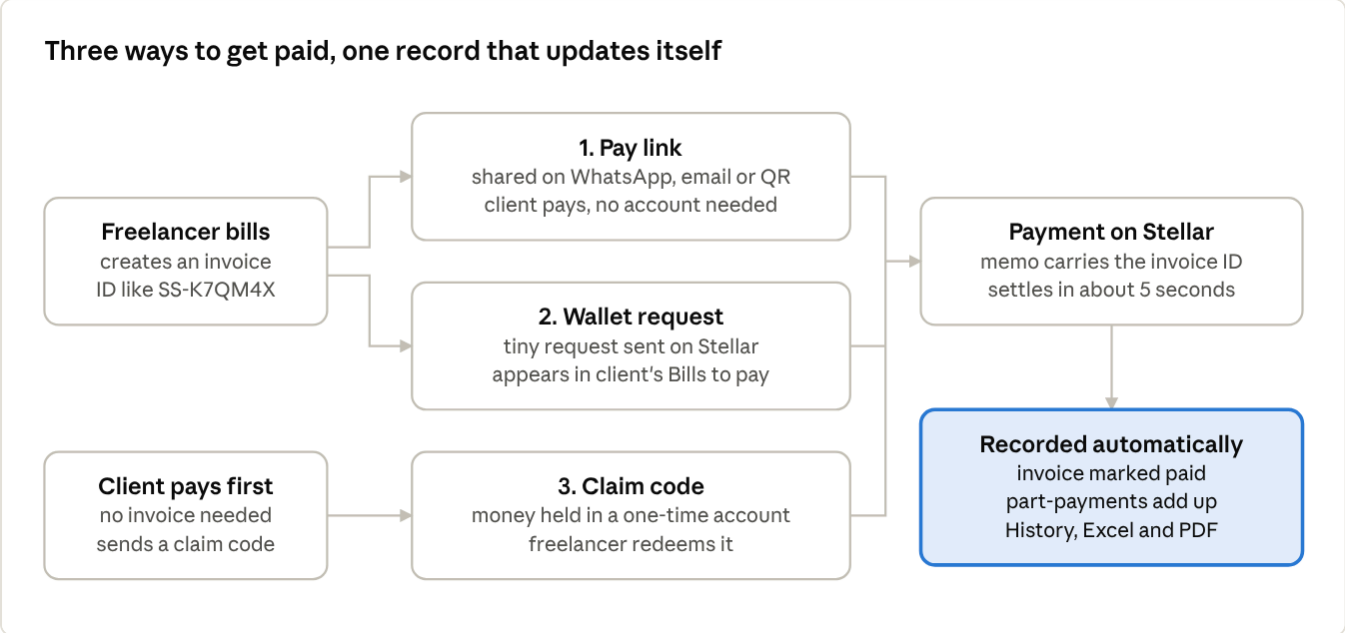

More and more developers, designers and contributors are paid in USDC by DAOs, grant programs and overseas clients. The money lands in their wallet with nothing tying it to the work it paid for.

- **"Which invoice was this for?"** A wallet shows an amount and a long address, not a client name or invoice number.
- **Part-payments and late payments** end up tracked by hand in spreadsheets.
- **Tax time is painful:** the freelancer rebuilds a year of payments, with the local-currency value on each day, from a block explorer.
- **The alternatives cost a lot:** bank wires and PayPal take 1 to 5 days and 3 to 5% plus FX; freelance marketplaces take 10 to 20%.

SettleSync fixes the matching problem at the source: the invoice ID travels inside the payment itself, so reconciliation is exact and automatic.

How it works

A freelancer can get paid three ways, and every one ends in the same place: a Stellar payment that SettleSync recognises and records by itself.

How SettleSync works: three ways to get paid

- **Pay link:** the invoice becomes a link (and QR code). The client opens it, connects any Stellar wallet and pays in one click.
- **Wallet request:** the freelancer enters the client's Stellar address. A tiny transaction carries the request, and it shows up in the client's **Bills to pay** on any device.
- **Claim code:** the client pays before any invoice exists. The money waits in a one-time Stellar account; the freelancer redeems the code, and the leftover deposit goes back to the client.
- **Auto-matching:** the invoice ID rides in the payment's memo. SettleSync watches the freelancer's wallet and marks the right invoice paid, adding up part-payments.
- **Records:** History with totals by period, a branded PDF invoice, and an Excel export with each payment's local-currency value on the day it arrived.

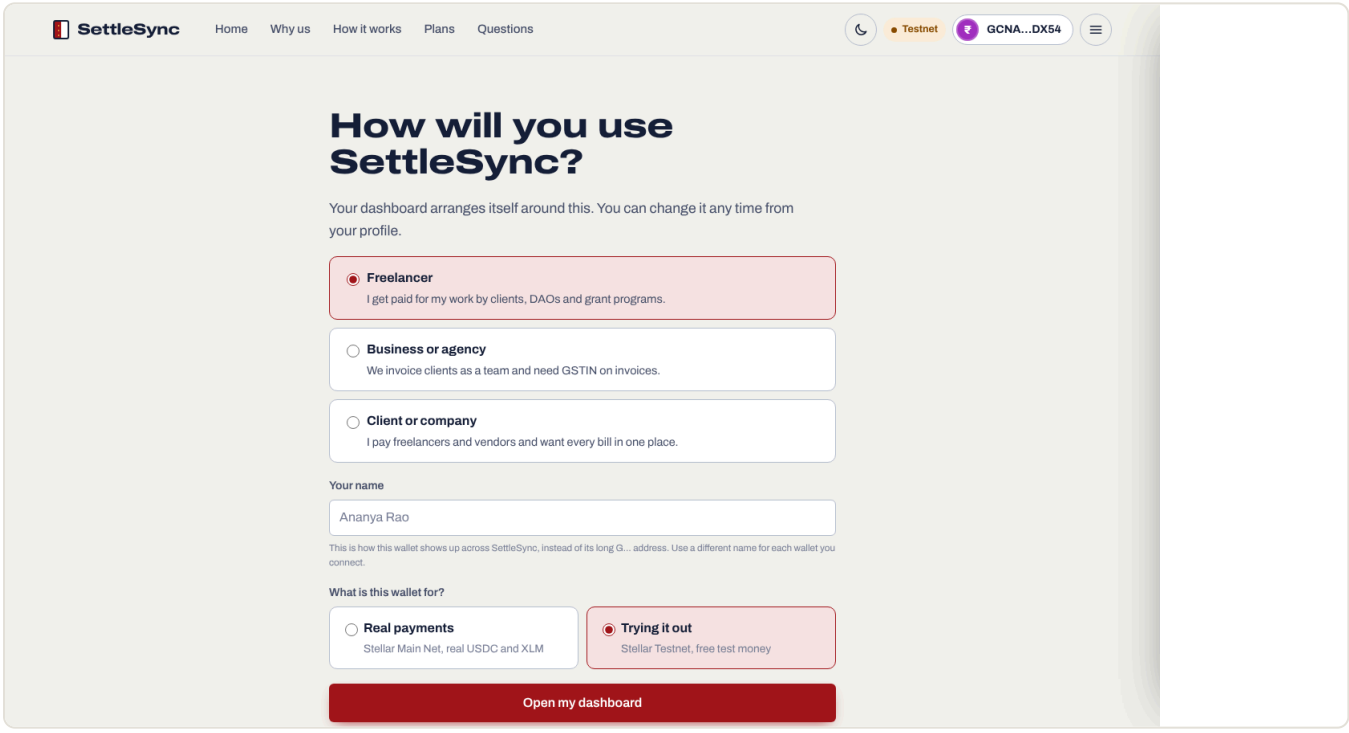

Two newer features build on this:

- **Part payments:** the freelancer can switch on part payments for an invoice, with an optional minimum per payment. The client pays an advance now and the rest later from the same link; every part is matched to the invoice.
- **Pay in any currency:** the client can pay with any asset in their wallet that Stellar can convert, for example XLM for a USDC invoice. Stellar converts it inside the same payment, so the freelancer receives exactly what was billed.

Set up in 5 minutes

Test on **Testnet** with free test money. You need two wallets: one acts as the **freelancer** (gets paid), the other as the **client** (pays). Use two browsers, or one normal window and one private window, so each holds a different wallet.

1. **Get a wallet.** Easiest: Albedo, which works in the browser with nothing to install. Or install Freighter and create two accounts in it.
2. **Put the wallet on Testnet.** In Freighter: Settings, Network, Test Net. Albedo asks per transaction. SettleSync follows the wallet's network automatically and shows a small "Testnet" chip in the header.
3. **Open the dashboard** at settlesync-silk.vercel.app/#/dashboard and click **Connect wallet**.
4. **Create a profile.** Pick a role (Freelancer for wallet A, Client for wallet B), type a display name, and under "What is this wallet for?" choose **Trying it out**.
5. **Add free test money.** On the dashboard, click **Testnet top-up**, then **Add test XLM** (10,000 XLM from Stellar's Friendbot). Click **Add test USDC** to swap some XLM into test USDC on Stellar's built-in exchange.
6. Repeat steps 3 to 5 for the second wallet in the other browser window.

Profile setup: role, display name, and Real payments or Trying it out

The first time you visit, a short opening animation plays once per session. It is skipped on pay and claim links.

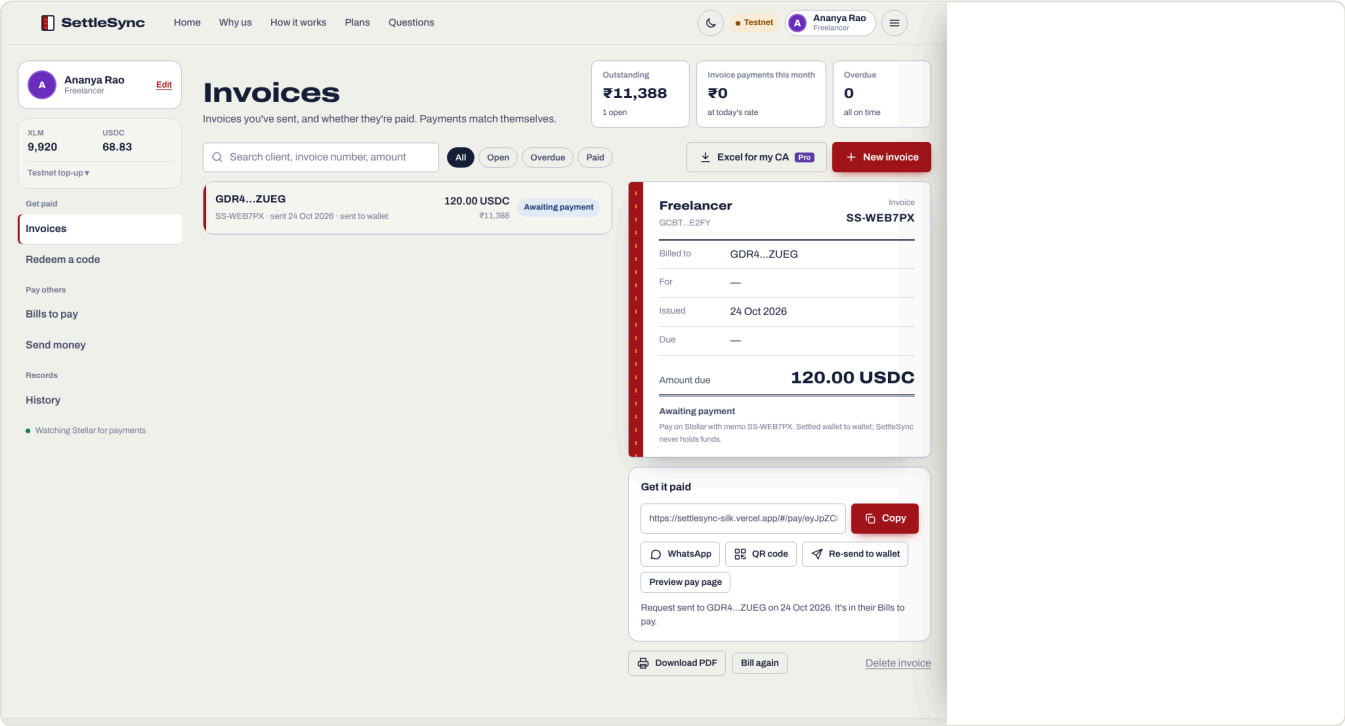

Test scripts

Nine short tests cover everything. Wallet A is the freelancer, wallet B is the client. Each payment settles in about 5 seconds; SettleSync checks Stellar every few seconds, so allow up to 15 seconds for a status to change.

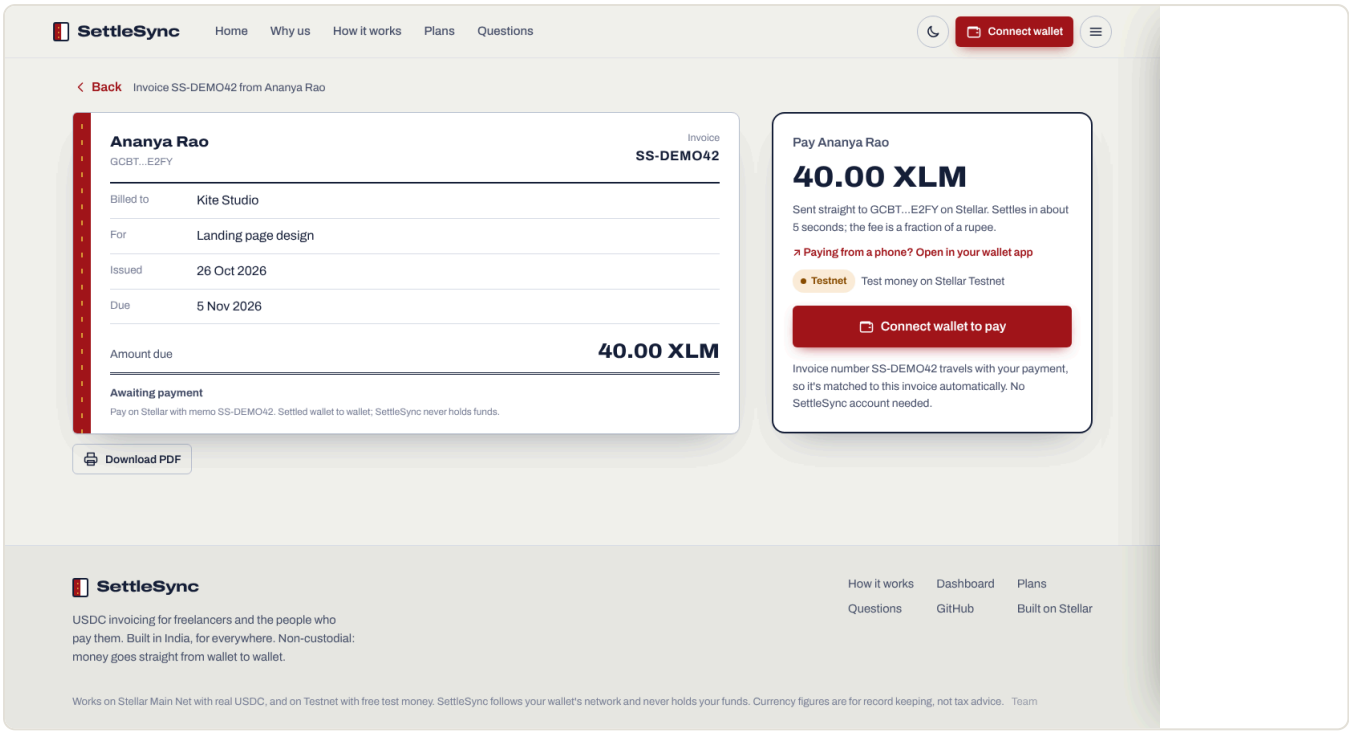

Test 1: Invoice paid by a pay link (main flow)

1. As **wallet A**, go to **My invoices** and click **New invoice**.
2. Fill in Billing (for example "Kite Studio"), For, Amount (try 40) and Paid in **XLM**. Choose **Pay link**, then **Create invoice**.
3. Open the new invoice. Under **Get it paid**, click **Copy**. WhatsApp, QR code and Preview pay page are also there.
4. In the **wallet B** browser, open the link, click **Connect wallet to pay**, then **Pay** and approve in the wallet.
5. Back in wallet A, watch the invoice.

- ☐ Wallet B sees a clean pay page with the amount, the freelancer's name and the invoice details
- ☐ Wallet A's invoice changes to **Paid** on its own, with a "Payment matched" notice and a link to the transaction

Invoice detail with the pay link, WhatsApp, QR code and Send to wallet

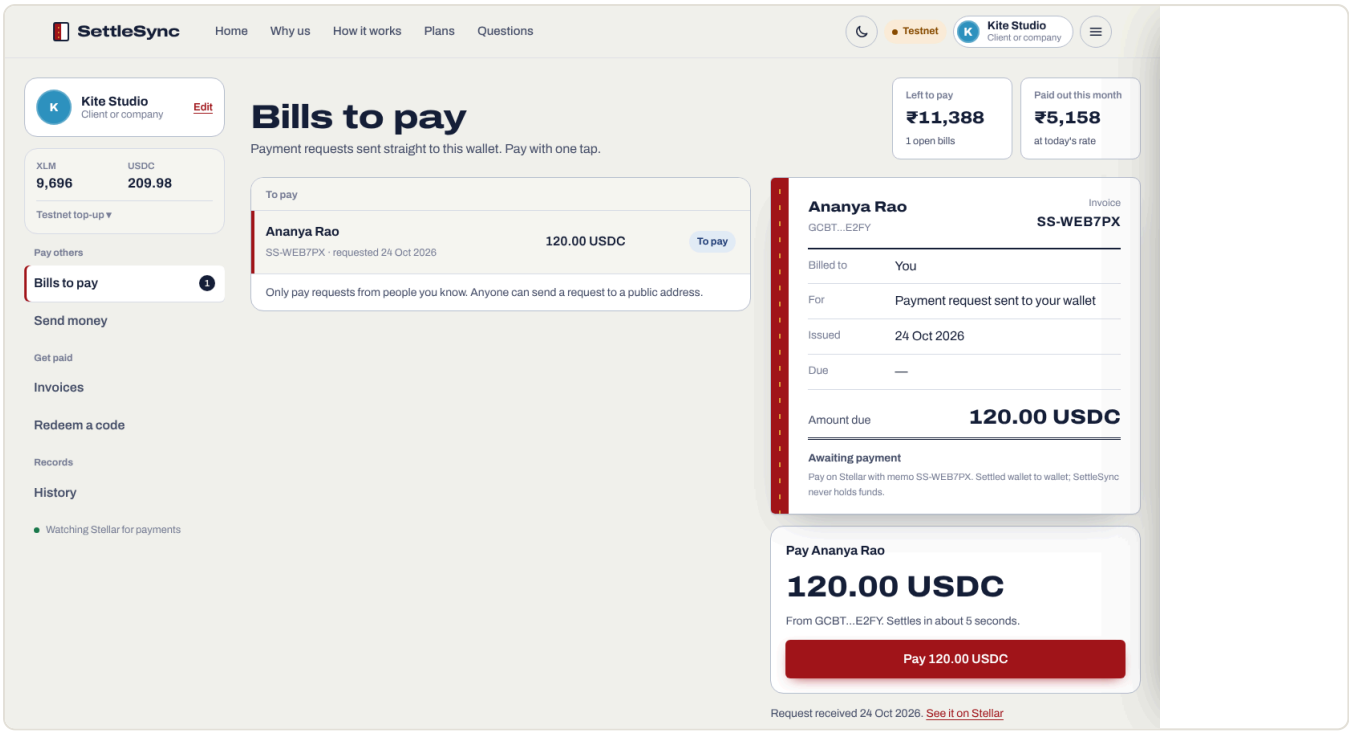

The pay page a client sees, no account needed

Test 2: Payment request straight to the client's wallet

1. Copy wallet B's address (G...) from its dashboard or wallet.
2. As wallet A, create a new invoice and choose **Send to their wallet**. Paste wallet B's address and click **Create and send**. Approve the tiny 0.0000001 XLM transaction that carries the request.
3. As wallet B, open **Bills to pay**. Select the bill and click **Pay**.

- ☐ The bill appears in wallet B with wallet A's **name**, not just an address
- ☐ After paying, it shows Paid in both dashboards
- ☐ It works even on a different device, because the request lives on Stellar, not on a server

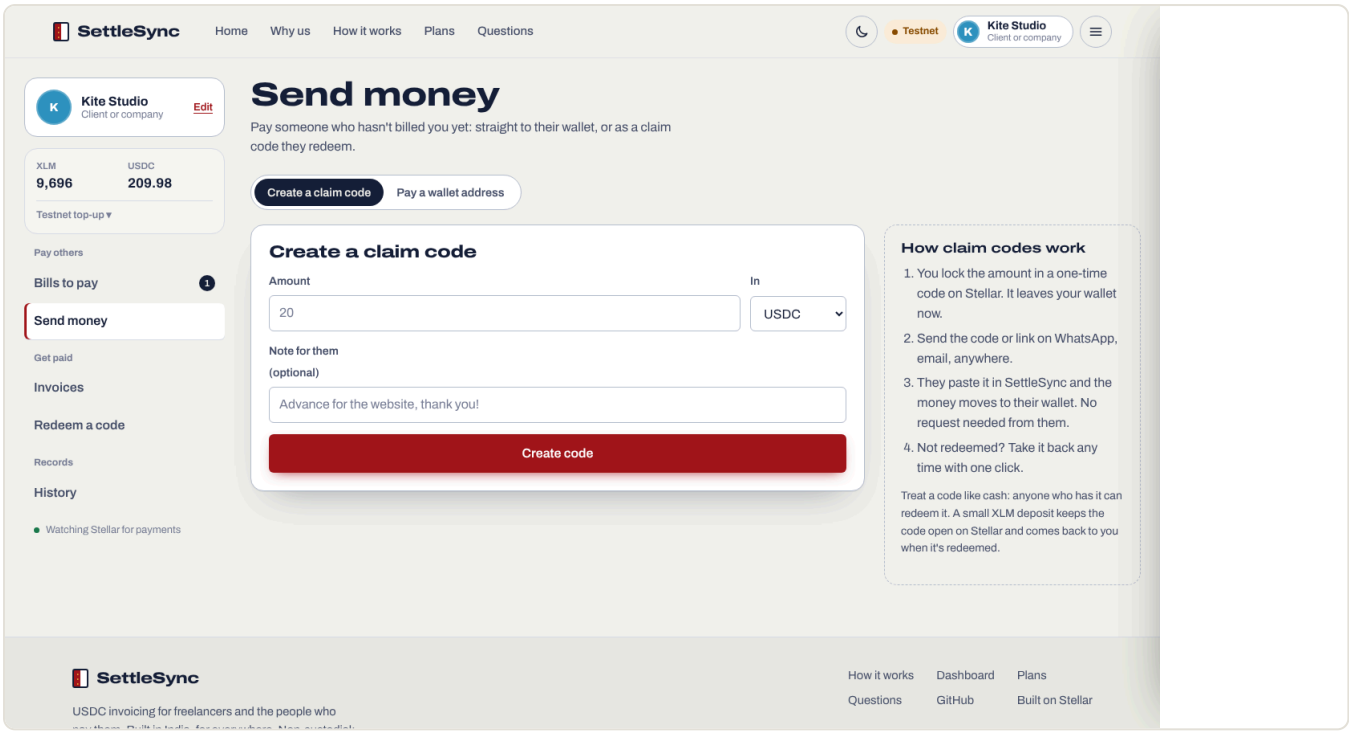

Bills to pay in the client dashboard

Test 3: Client pays first with a claim code

1. As wallet B, open **Send money**, then **Create a claim code**. Enter an amount (try 5 XLM) and a note. Click **Create code** and approve.
2. Click **Copy claim link** and open it in the wallet A browser.
3. As wallet A, click **Redeem**. Or paste the code under **Redeem a code** in the dashboard.
4. Create a second code and, as wallet B, use **Take the money back** under **Your claim codes**.

- ☐ Wallet A receives the money in about 5 seconds
- ☐ A redeemed link then says "Nothing left to claim"
- ☐ Taking back an unredeemed code returns the money to wallet B

Send money: create a claim code

Test 4: Pay any wallet directly

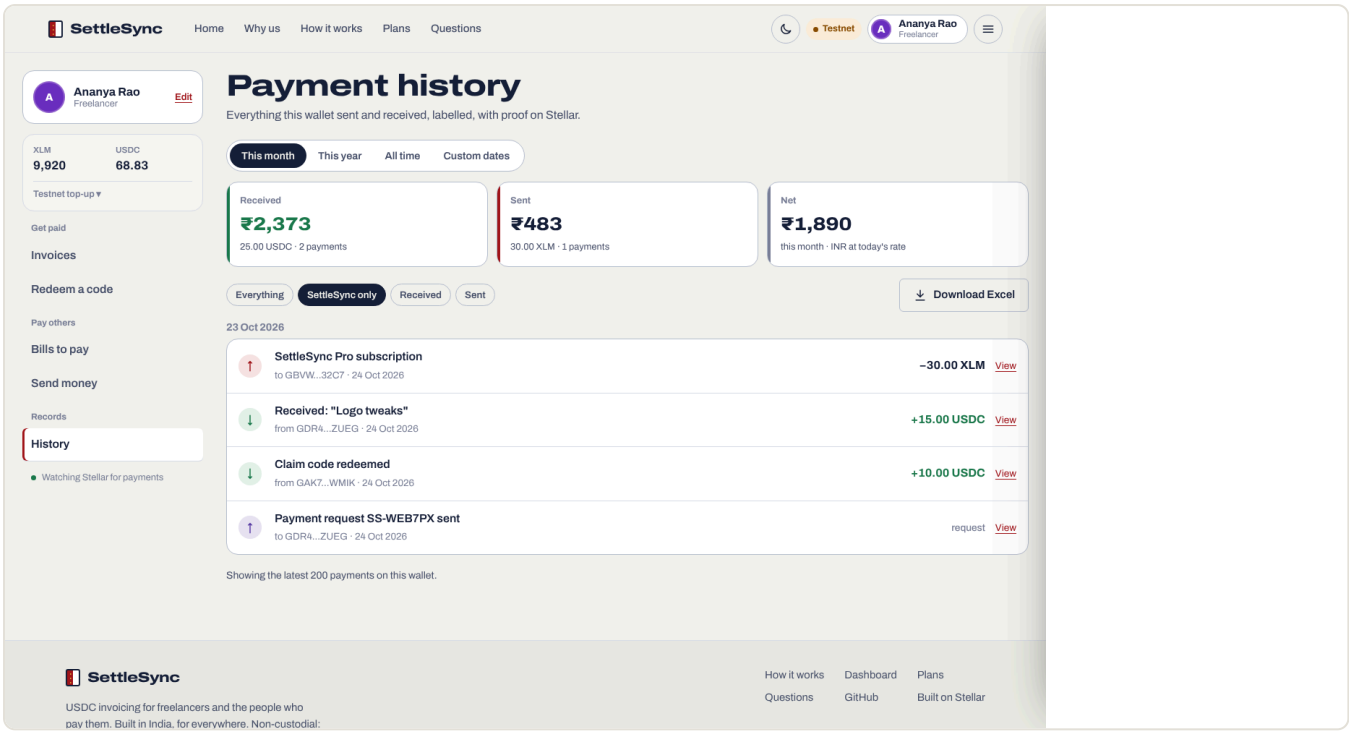

1. As wallet B, open **Send money**, then **Pay a wallet address**.
2. Paste wallet A's address, an amount, and a note such as "Logo, October". Click **Send**. Only hold XLM? Choose XLM under **Pay with** and they still receive USDC.

- ☐ The payment shows in both wallets' **History** with the note as its label

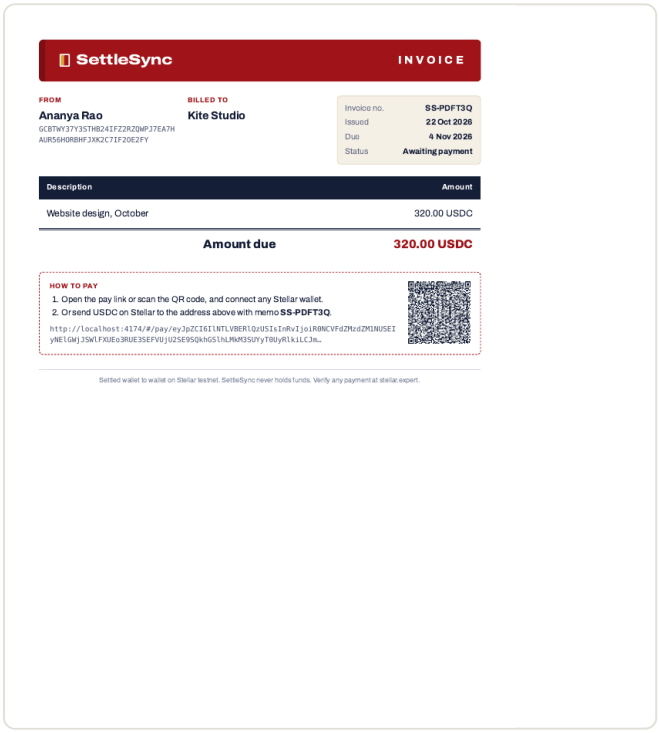

Test 5: Records, PDF and accountant export

1. Open **History**. Switch between **This month**, **This year**, **All time** and **Custom dates**.
2. Click **Download Excel**.
3. Open any invoice and click **Download PDF** (choose "Save as PDF" in the print dialog).
4. On My invoices, click **Excel for my CA**.

- ☐ Totals for received, sent and net change with the period
- ☐ The Excel file has formatted columns, totals in local currency and a link to each transaction
- ☐ The PDF is a one-page branded A4 invoice with a pay QR code

Payment history with period totals

Invoice PDF

Excel export for the accountant

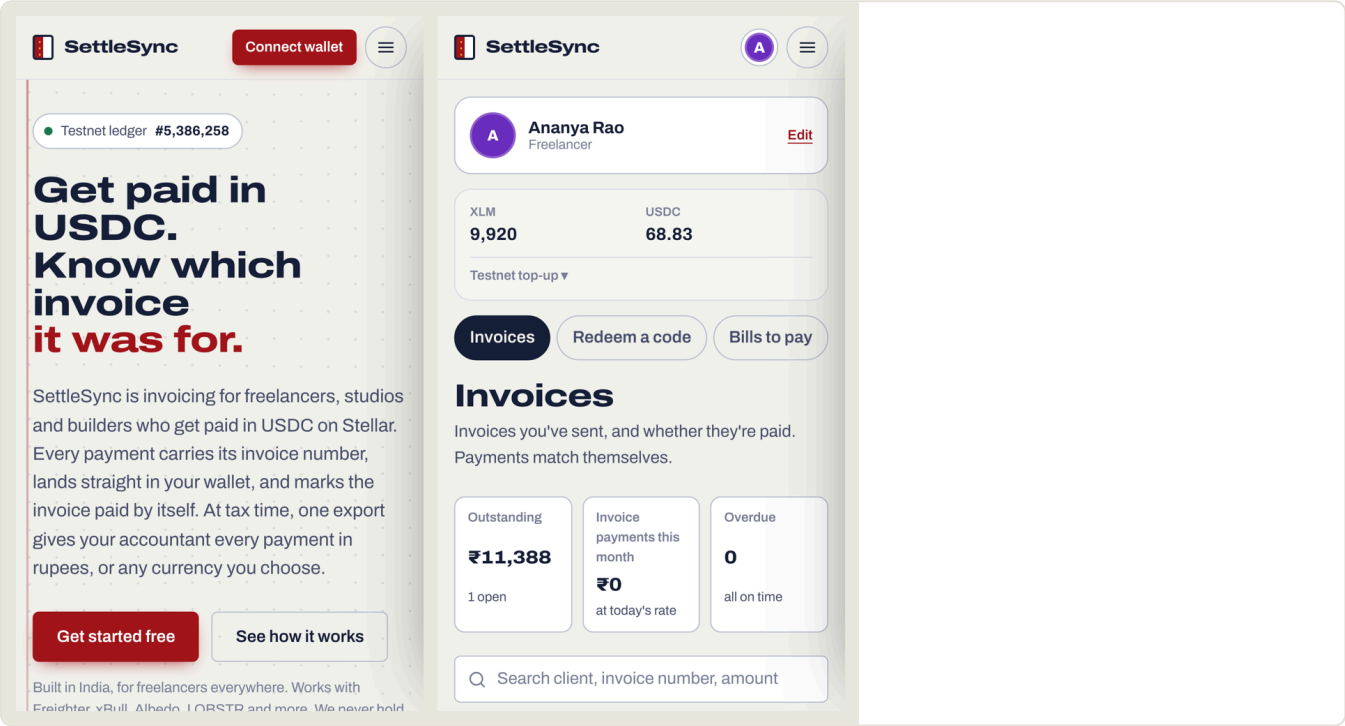

Test 6: Main Net (optional, real money)

Switch the wallet to **Main Net**; SettleSync follows it and the header chip changes to "Main Net". Repeat Test 1 with a very small amount, such as 1 XLM. Invoices and codes are kept separately for each network. You can also switch from the account menu (click your name).

- ☐ The site switches network on its own when the wallet does
- ☐ A pay link made on Main Net opens on Main Net for the payer

Test 7: Mobile, dark mode and the rest

- ☐ Open the site on a phone (iPhone or Android): menu, dashboard and pay page fit the screen
- ☐ Toggle dark mode with the moon icon in the header
- ☐ Account page (click your name): change display name, local currency (INR, USD, EUR, GBP, AED, SGD, NGN, BRL, PHP) and role
- ☐ Account page: download a backup and restore it

Phone layout: home page and dashboard

Test 8: Part payments (new)

1. As wallet A, click **New invoice**. Bill 30 **USDC**, turn on the **Allow part payments** switch, and set **Minimum per payment** to 5. Create it with **Pay link** (or **Send to their wallet** to wallet B).
2. As wallet B, open the link (or the bill in **Bills to pay**). Under **How much are you paying now?**, type 10 and pay.
3. Pay again with the remaining 20 (the **Full** button fills it in).

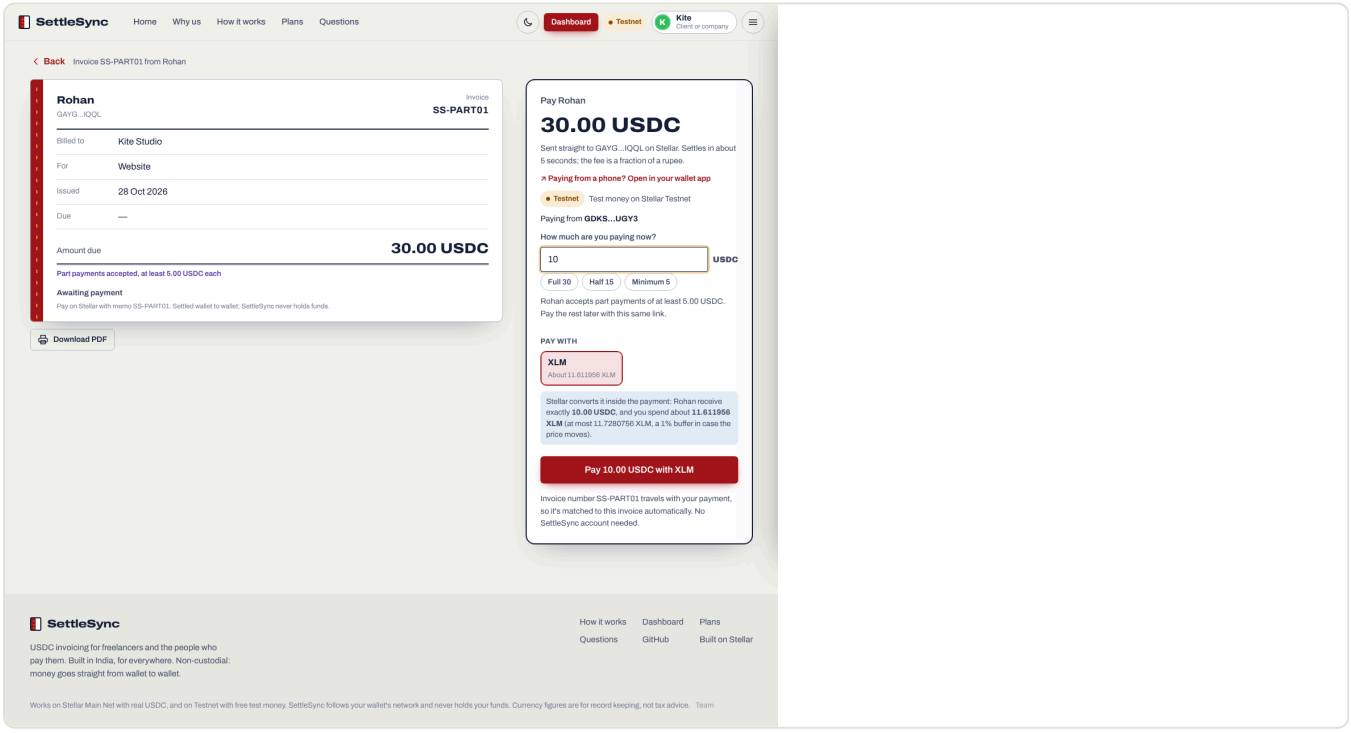

- ☐ The invoice says "Part payments accepted, at least 5.00 USDC each"
- ☐ Typing 3 shows "The minimum for each payment is 5.00 USDC"; typing 40 shows it's more than what's left
- ☐ After the first payment, the invoice shows **Part paid** with 20 USDC left, on both sides, and the rest waits in wallet B's **Bills to pay** (no need to open the link again)
- ☐ After the second payment, it's stamped **Paid**

Test 9: Pay in any currency (new)

Stellar can convert currencies inside a single payment (a path payment). The client pays with what they hold; the freelancer receives exactly the invoiced amount.

1. Use a client wallet that holds **only XLM** (a fresh wallet with just Add test XLM, no USDC).
2. As wallet A, create a 10 USDC invoice and open its pay link as that client.
3. Under **Pay with**, XLM is offered with its price ("About 11.6 XLM"). Click **Pay 10.00 USDC with XLM**.
4. Also try the reverse: an XLM invoice paid with USDC.

- ☐ The page shows the price before paying, and the most it can cost (1% buffer)
- ☐ Wallet A receives exactly 10 USDC, and the invoice is matched and stamped Paid
- ☐ Wallet A's **History** shows "they paid … XLM, converted"
- ☐ The client never needed to turn on USDC

Paying part of a USDC invoice with XLM: the client picks the amount and what to pay with

Why SettleSync

SettleSync is the only option here that knows which invoice each payment was for, settles in seconds for under a cent, and leaves the money in the freelancer's own wallet.

	SettleSync	Plain wallet transfer	Bank wire / PayPal	Freelance marketplace
Knows which invoice a payment was for	Automatic, by memo	By hand	Reference often missing	Inside the platform only
Time to settle	About 5 seconds	Seconds	1 to 5 days	Days
Cost to get paid	Under 0.01 INR network fee	Network fee	3 to 5% plus FX	10 to 20% commission
Client can pay before an invoice exists	Claim codes	Only with your address	Yes	No
Pay in parts, tracked automatically	With a minimum you set	By hand	Tracked by hand	Milestones on some
Client pays in a different currency	Converted inside the payment	Only the asset you accept	With 3 to 5% FX costs	Card or bank only
Accountant export in local currency	One click	No	Statements only	Platform reports
Who holds the money	You	You	Bank / PayPal	Platform

What makes it different from other Stellar payment tools:

- **Three ways to get paid** in one place: pay link, on-chain request to a wallet, or a claim code the client can send first.
- **No backend database for payments.** Requests, names and subscriptions are read from Stellar, so they follow the user to any device.
- **Names, not addresses:** people publish a display name on their own Stellar account.
- **Built for tax time:** each payment's local-currency value on the day it arrived.
- **Business model:** a Pro plan at 299 INR (or 3 USDC) a month, paid on-chain. SettleSync never takes a cut of payments.

How it uses Stellar

Every feature runs directly on Stellar. Each transaction is built in the browser and approved in the user's own wallet; there is no server holding keys or money.

Stellar feature	What SettleSync uses it for	Where to see it
Payments with a text memo	Invoice ID travels inside the payment, so it matches the right invoice automatically	Test 1
Memo-encoded request (0.0000001 XLM, memo `R:<id>:<amount>:<asset>`)	Sends a bill straight to a client's wallet with no server	Test 2, Bills to pay
One-time account, co-signed, then account merge	Claim codes: money locked in a fresh account, redeemed to the recipient, deposit merged back to the payer	Test 3
Path payment (strict receive)	Client pays with any asset they hold; Stellar's exchange converts it inside the payment, and the freelancer receives the exact invoice amount	Test 9
`manageData` (`ss.name`)	Display name stored on the user's own account	Names in Bills to pay
`changeTrust`	One-click USDC trustline	Dashboard setup box
Path payment (strict send)	Swap test XLM into test USDC on Stellar's built-in exchange	Add test USDC
Circle USDC and XLM	The two assets invoices can be paid in	All tests
Horizon payments API	Watches incoming payments and builds History	Invoices, History
SEP-7 `web+stellar:pay` links	Mobile wallets open the payment with amount and memo filled in	Pay page
Stellar Wallets Kit	Freighter, Albedo, xBull, LOBSTR, Hana, Rabet and more	Connect wallet
Main Net and Testnet	Follows the wallet's network; links carry their network	Test 6
Pro payment to treasury (memo `PRO:1M`)	30-day subscription recorded on-chain	Plans page

The idea was checked against Stellar's ecosystem data through Raven and Stellar Light. The closest projects (DeFa by InvoiceMate, FeePrime, Bloccpay, Bitwage) focus on invoice financing or payroll; none does memo-matched invoicing with claim codes and accountant exports for individual freelancers.

Known limitations

These are known and expected during the pilot, so testers need not report them as bugs.

- **Wallet warning on Main Net:** Freighter may show "This site was flagged as malicious" for new `vercel.app` addresses. This comes from the wallet's scanner for new domains, not from SettleSync. A custom domain is planned.
- **Pro on Main Net is off:** no Main Net treasury yet, so Pro shows "Free for everyone during the pilot". On Testnet, Pro can be bought with test money.
- **Invoices are stored in the browser:** invoices made with a pay link live in that browser. Use **Account**, backup and restore to move them. Wallet requests are restored from Stellar automatically.
- **Opening a pay link in the same browser as the freelancer** works, but switch wallets to pay; two browsers make testing clearer.
- **Local-currency values** come from CoinGecko and are for record keeping, not tax advice.
- **Owner dashboard:** there is a hidden revenue page for the SettleSync team at #/owner, reached from "Team" in the footer. It needs a passcode, shared on request.

Roadmap and feedback

If the pilot proves useful, this is what we build next (also on the website under What's next):

1. **Milestone escrow (next):** the client locks the full amount in a Soroban smart contract; each milestone's share is released when approved
2. **Split payouts for teams (next):** one invoice, paid once, shared out automatically (say 60/40) in the same Stellar transaction
3. **Retainers (planned):** monthly invoices that create and send themselves, with reminders
4. **Cash out to your bank (planned):** USDC to rupees or local currency through regulated Stellar anchors
5. **Invoices on every device (planned):** encrypted sync
6. **More currencies to bill in (exploring):** EURC and other Stellar stablecoins
7. Also: a Main Net treasury wallet so Pro can be paid on Main Net, and a custom domain

When you send feedback, these answers help most:

Question	Your answer
Which wallet and browser did you use?	
Which tests did you complete?	
Anything that didn't work? (screenshot and the step number help)	
Anything confusing or unclear?	
Would you use this, or recommend it to a freelancer?
